

Low voltage 16-bit constant current LED sink driver with output error detection and auto power-saving for automotive applications

Datasheet - production data

Description

The STAP16DPS05 is a monolithic, low voltage, low current power 16-bit shift register designed for LED panel displays. The device contains a 16-bit serial-in, parallel-out shift register that feeds a 16-bit D-type storage register. In the output stage, sixteen regulated current sources are designed to provide 5-100 mA constant current to drive the LEDs.

The STAP16DPS05 features the open and short LED detections on the outputs. The STAP16DPS05 ensures the backward compatibility with the STP16C/L596. The detection circuit checks 3 different conditions, which can occur on the output line: short to GND, short to V_O or open line. The data detection results are loaded in the shift register and shifted out via the serial line output. The detection functionality is implemented without increasing the pin number. Through a secondary function of the output enable and latch pin (DM1 and DM2 respectively), a dedicated logic sequence allows the device to enter or leave detection mode. Through an external resistor, users can adjust the output current of the STAP16DPS05, thus controlling the light intensity of the LEDs. In addition, the user can adjust the intensity of the brightness of the LEDs from 0% to 100% through the $\overline{OE/DM2}$ pin. The STAP16DPS05 guarantees a 20 V output driving capability, allowing users to connect more LEDs in series. The high clock frequency, 30 MHz, also satisfies the system requirement of high volume data transmission. The 3.3 V of voltage supply is very useful for applications that interface any microcontroller from 3.3 V micro. Compared with a standard TSSOP package, the TSSOP exposed pad increases the capability of heat dissipation by a factor of 2.5.

Features

- AECQ100 qualification
- Low voltage power supply down to 3 V
- 16 constant current output channels
- Adjustable output current through external resistor
- Short and open output error detection
- Serial data IN/parallel data OUT
- 3.3 V micro driver-able
- Output current: 5-100 mA
- Auto power-saving
- Max. clock frequency: 30 MHz
- 20 V current generator rated voltage
- Power supply voltage: from 3 V to 5.5 V
- Thermal shutdown for overtemperature protection
- ESD protection 2.0 kV HBM

Applications

- Dashboard and infotainment backlighting
- Exterior/interior lighting
- DTRLs

2 Electrical ratings

2.1 Absolute maximum ratings

Stressing the device above the rating listed in the “absolute maximum ratings” table may cause permanent damage to the device. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the operating sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Note: Latch and output enable are level-sensitive and they are not synchronized with rising or falling edge of CLK signal. When LE/DM1 terminal is low level, the latch circuits hold the previous set of data. When LE/DM1 terminal is high level, the latch circuits refresh new set of data from SDI chain. When OE/DM2 terminal is at low level, the output terminals - Out0 to Out15 respond to data in the latch circuits, either '1' ON or '0' OFF. When OE/DM2 terminal is at high level, all output terminals are switched OFF.

7 Detection mode functionality

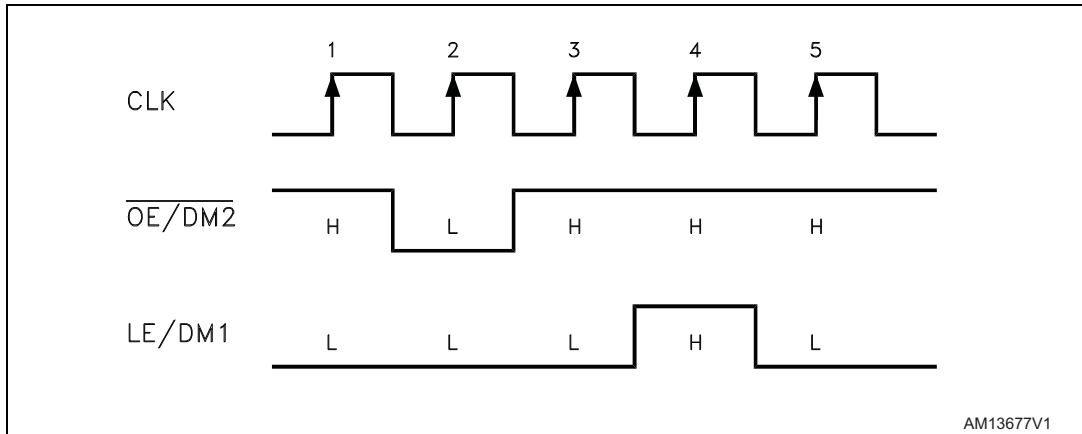

7.1 Phase one: “entering in detection mode“

From the “normal mode” condition the device can switch to the “error mode” by a logic sequence on the $\overline{OE}/DM2$ and $LE/DM1$ pins as shown in the following table and diagram:

Table 12. Entering in detection truth table

CLK	1°	2°	3°	4°	5°
$\overline{OE}/DM2$	H	L	H	H	H
$LE/DM1$	L	L	L	H	L

Figure 14. Entering in detection timing diagram

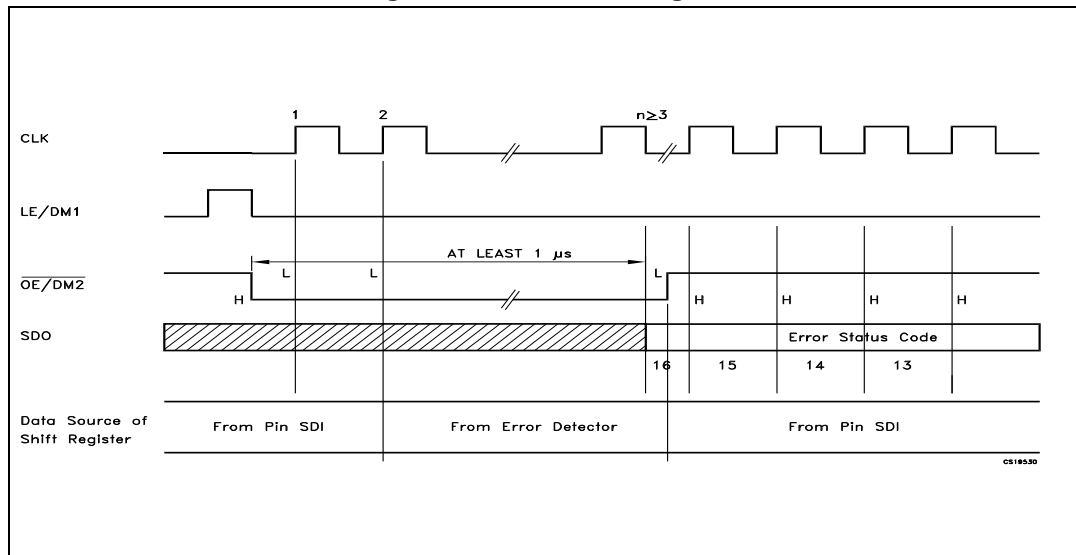

After these five CLK cycles the device goes into the “error detection mode” and at the 6th rising edge of CLK the SDI data are ready for sampling.

7.2 Phase two: “error detection”

The 16 data bits must be set to “1” in order to set ON all the outputs during the detection. The data are latched by LE/DM1 and after that the outputs are ready for the detection process. When the microcontroller switches the OE/DM2 to LOW, the device drives the LEDs in order to analyze if an OPEN or SHORT condition has occurred.

Figure 15. Detection diagram

The LED status is detected at least in 1 microsecond (minimum) and after this time the microcontroller sets OE/DM2 in high state and the output data detection result goes to the microprocessor via SDO.

Detection mode and normal mode both use the same data format. As soon as all the detection data bits are available on the serial line, the device may go back to normal mode of operation. To re-detect the status, the device must go back in normal mode and re-enter error detection mode.

Figure 16. Timing example for open and/or short detection

7.3 Phase three: “resuming to normal mode”

The sequence for re-entering in normal mode is shown in the following table and diagram:

Figure 17. Resuming to normal mode timing diagram

CLK	1°	2°	3°	4°	5°
$\overline{\text{OE/DM2}}$	H	L	H	H	H
LE/DM1	L	L	L	L	L

Note: For proper device operation the “entering in detection” sequence must be followed by a “resume mode” sequence, it is not possible to insert consecutive equal sequences.

7.4 Error detection conditions

$V_{DD} = 3.3$ to 5 V temperature range -40 to 125 °C

Table 13. Detection conditions

Configuration	Detection mode	Detection results		
SW-1 or SW-3b	Open line or output short to GND detected	$\implies I_{ODEC} \leq 0.5 \times I_O$	No error detected	$\implies I_{ODEC} \geq 0.5 \times I_O$
SW-2 or SW-3a	Short on LED or short to V-LED detected	$\implies V_O \geq 2.4 \text{ V}$	No error detected	$\implies V_O \leq 2.2 \text{ V}$

Note: Where: I_O = the output current programmed by the R_{EXT} , I_{ODEC} = the detected output current in detection mode.

Figure 18. Detection circuit

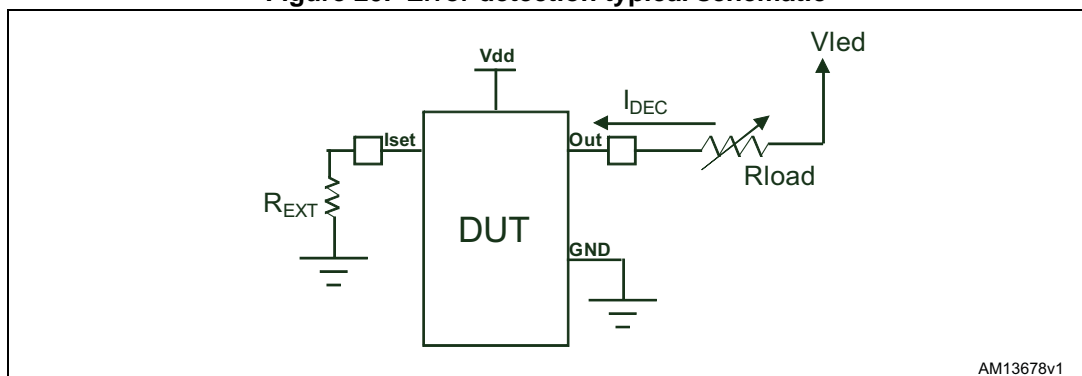

Figure 19. Error detection sequence

Typical schematic used to perform the error detection:

Figure 20. Error detection typical schematic

I_{ODEC} can be measured as follows:

$$I_{ODEC} = (V_{led} - V_{load}) / R_{load}$$

Table 14 and Table 15 show respectively the I_{ODEC} average value at 3.3 V and 5.0 V.

The I_{ODEC} is the current value recognized by the device output open error detection.

7.5 Auto power-saving

The auto power-saving feature minimizes the quiescent current if no active data is detected on the latches and auto powers-up the device as the first active data is latched.

Figure 21. Auto power-saving feature

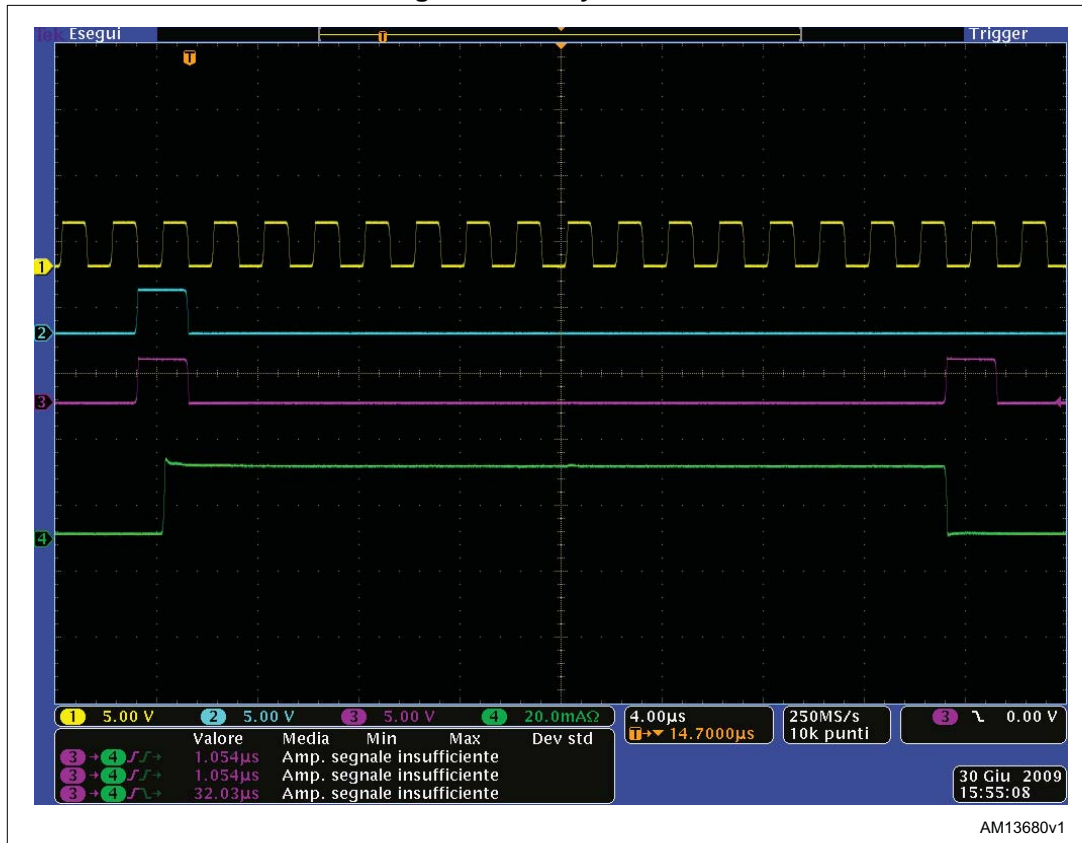

Conditions:

- Temp. = 25 °C, $V_{DD} = 3.3$ V, $V_{in} = V_{DD}$, $V_{Led} = 3.0$ V, $I_{set} = 20$ mA
- Ch1 (yellow) = I_{DD} , Ch2 (blue) = SDI, Ch3 (purple) = LE/DM1, Ch4 (green) = CLK

I_{dd} consumption:

- I_{dd} (normal operation) = 5.15 mA
- I_{dd} (shutdown condition) = 163 μ A

Figure 22. Delay LE-OUT

After 16 clock cycles without data change, the auto power-saving mode starts as expected. Delay TLE-OUT = 1.053 μs

Conditions:

- Temp. = 25 °C, V_{DD} = 3.3 V, V_{in} = V_{DD}, V_{Led} = 3.0 V, I_{set} = 20 mA
