

## Serial Interface Adapter for TC500 A/D Converter Family

### Features

- Converts TC500/TC500A/TC510/TC514 to Serial Operation
- Programmable Conversion Rate and Resolution for Maximum Flexibility
- Supports up to 17-Bits of Accuracy Plus Polarity Bit
- Low Power Operation: Typically 7.5mΩ
- 14-Pin PDIP or 16-Pin SOIC Packages
- Polled or Interrupt Mode Operation

### Applications

- Computer Peripheral Interface
- Portable Instruments
- Data Acquisition System Interface

### Device Selection Table

Part Number	Package	Temperature Range
TC520ACOE	16-Pin SOIC (Wide)	0°C to +70°C
TC520ACPD	14-Pin PDIP	0°C to +70°C

### Package Type

### General Description

The TC520A serial interface adapter provides logic control for Microchip's TC500/TC500A/TC510/TC514 family of dual slope, integrating A/D converters. It directly manages TC500 converter phase control signals A, B and CMPTR, thereby reducing host processor task loading and software complexity. Communication with the TC520A is accomplished over a 3 wire serial port. Key converter operating parameters are programmable for complete user flexibility. Data conversion is initiated when the  $\overline{\text{CE}}$  input is brought low. The converted data (plus overrange and polarity bits) are held in an 18-bit shift register until read by the processor or until the next conversion is completed. Data may be clocked out of the TC520A at any time, and at any rate, the user prefers. A Data Valid ( $\overline{\text{DV}}$ ) output is driven active at the start of each conversion cycle, indicating the 18-bit shift register update has just been completed. This signal may be polled by the processor or can be used as data ready interrupt. The TC520A timebase can be derived from an external frequency source of up to 6MHz or can operate from its own external crystal. It requires a single 5V logic supply and dissipates less than 7.5mΩ.

# TC520A

## Functional Block Diagram

## 2.0 PIN DESCRIPTIONS

The descriptions of the pins are listed in Table 2-1

**TABLE 2-1: PIN FUNCTION TABLE**

Pin Number 14-Pin PDIP	Pin Number 16-Pin SOIC	Symbol	Description
1	1	V <sub>DD</sub>	Input. +5V ±10% power supply input with respect to DGND.
2	2	DGND	Input. Digital Ground.
3	3	CMPTR	Input, active high or low (depending on polarity of the voltage input to A/D converter). This pin connects directly to the zero crossing comparator output (CMPTR) of the TC5XX A/D converter. A high-to-low state change on this pin causes the TC520A to terminate the de-integrate phase of conversion.
4	4	B	Output, active high. The A and B outputs of the TC520A connect directly to the A and B inputs of the TC5XX A/D converter connected to the TC520A. The binary code on A, B determines the conversion phase of the TC5XX A/D converter: (A, B) = 01 places the TC5XX A/D converter into the Auto Zero phase; (A, B) = 10 for Integrate phase (INT); (A, B) = 11 for De-integrate phase (DINI) and (A, B) = 00 for Integrator Zero phase (IZ). Please see the TC500/TC500A/TC510/TC514 family data sheets for a complete description of these phases of operation.
5	5	A	Output, active high. See pin 4 description above.
6	6	OSC <sub>OUT</sub>	Input. This pin connects to one side of an AT-cut crystal having a effective series resistance of 100Ω (typ.) and a parallel capacitance of 20pF (typ.). If an external frequency source is used to clock the TC520A, this pin must be left floating.
7	7	OSC <sub>IN</sub>	Input. This pin connects to the other side of the crystal described in pin 6 above. The TC520A may also be clocked from an external frequency source connected to this pin. The external frequency source must be a pulse train having a duty cycle of 30% (minimum); rise and fall times of 15nsec and a min/max amplitude of 0 to V <sub>IH</sub> . If an external frequency source is used, pin 6 must be left floating. A maximum operating frequency of 4MHz (crystal) or 6MHz (external clock source) is permitted.
	8	N/C	No connection on 16 pin package version.
	9	N/C	No connection on 16 pin package version.
8	10	READ	Input, active low, level and negative edge triggered. A high-to-low transition on <u>READ</u> loads serial port output shift register with the most recent converted data. Data is loaded such that the first bit transmitted from the TC520A to the processor is the OVERRANGE bit (OVR), followed by the POLARITY bit (POL) (high = input positive; low = input negative). This is followed by a 16-bit data word (MSB first). OVR is available at the D <sub>OUT</sub> as soon as <u>READ</u> is brought low. This bit may be used as the 17th data bit, if so desired. The D <sub>OUT</sub> pin of the serial port is enabled only when <u>READ</u> is held low. Otherwise, D <sub>OUT</sub> remains in a high impedance state. A serial port read access cycle is terminated at any time by bringing <u>READ</u> high.
9	11	D <sub>OUT</sub>	Output, logic level. Serial port output pin. This pin is enabled only when <u>READ</u> is low (see <u>READ</u> pin description).
10	12	D <sub>CLK</sub>	Input, positive and negative edge triggered. Serial port clock. With <u>READ</u> low, serial data is clocked into the TC520A at each low-to-high transition of D <sub>CLK</sub> , and clocked out of the TC520A on each high-to-low transition of D <sub>CLK</sub> . A maximum serial port D <sub>CLK</sub> frequency of 3MHz is permitted.
11	13	D <sub>IN</sub>	Input, logic level. Serial port input pin. The TC5XX A/D converter integration time (T <sub>INT</sub> ) and Auto Zero time (TAZ) values are determined by the LOAD VALUE byte clocked into this pin. This initialization must take place at power up and can be rewritten (or modified and rewritten) at any time. The LOAD VALUE is clocked into D <sub>IN</sub> MSB first.

**TABLE 2-1: PIN FUNCTION TABLE (CONTINUED)**

Pin Number 14-Pin PDIP	Pin Number 16-Pin SOIC	Symbol	Description
12	14	$\overline{\text{LOAD}}$	Input, active low; level and edge triggered. The LOAD VALUE is clocked into the 8-bit shift register on board the TC520A while $\overline{\text{LOAD}}$ is held low. The LOAD VALUE is then transferred into the TC520A internal timebase counter (and becomes effective) when $\overline{\text{LOAD}}$ is returned high. If so desired, $\overline{\text{LOAD}}$ can be momentarily pulsed low, eliminating the need to clock a LOAD VALUE into $D_{\text{IN}}$ . In this case, the current state of $D_{\text{IN}}$ is clocked into the TC520A timebase counter selecting either a count of 65536 ( $D_{\text{IN}} = \text{High}$ ), or count of 32768, ( $D_{\text{IN}} = \text{Low}$ ).
13	15	$\overline{\text{DV}}$	Output, active low. $\overline{\text{DV}}$ is brought low any time the TC520A is in the AZ phase of conversion. This occurs when, either the TC520A initiates a normal AZ phase by setting A, B, equal to 01, or when $\overline{\text{CE}}$ is pulled high, which overrides the normal A, B sequencing and forces an AZ state. $\overline{\text{DV}}$ is returned high when the TC520A exits AZ.
14	16	$\overline{\text{CE}}$	Input, active low, level triggered. Conversion will be continuously performed as long as $\overline{\text{CE}}$ remains low. Pulling $\overline{\text{CE}}$ high causes the conversion process to be halted and forces the TC520A into the AZ mode for as long as $\overline{\text{CE}}$ remains high. $\overline{\text{CE}}$ should be taken high whenever it is necessary to momentarily suspend conversion (for example: to change the address lines of an input multiplexer). $\overline{\text{CE}}$ should be pulled high only when the TC520A enters an AZ phase (i.e. when $\overline{\text{DV}}$ is low). This is necessary to avoid excessively long integrator discharge times, which could result in erroneous conversion. This pin should be grounded if unused. It should be left floating if a 0.01 $\mu\text{F}$ RESET capacitor is connected to it (see Section 4.0, Typical Applications).

# TC520A

---

## 3.0 DETAILED DESCRIPTION

### 3.1 TC520A Timing

The TC520A consists of a serial port and state machine. The state machine provides control timing to the TC5xx A/D converter connected to the TC520A as well as providing sequential timing for TC520A internal operation. All timing is derived from the frequency source at  $OSC_{IN}$  and  $OSC_{OUT}$ . This frequency source can be either an externally provided clock signal or external crystal. If an external clock is used, it must be connected to the  $OSC_{IN}$  pin and  $OSC_{OUT}$  must remain floating. If a crystal is used, it must be connected between the  $OSC_{IN}$  and  $OSC_{OUT}$  and be physically located as close to the  $OSC_{IN}$  and  $OSC_{OUT}$  pins as possible. The incoming frequency is internally divided by 4 and the resulting clock (SYSCLK) controls all timing functions.

### 3.2 TC5XX A/D Converter Control Signals

The TC520A control outputs (A, B) and control input (CMPTR) connect directly to the corresponding pins of the TC5XX A/D converter. A conversion is consummated when A, B have been sequenced through the required 4 phases of conversion: Auto Zero (AZ), Integrate (INT), De-integrate ( $D_{INT}$ ) and Integrator Zero (IZ) (see Figure 4-1). The Auto Zero phase compensates for offset errors in the TC5XX A/D converter. The Integrate phase connects the voltage to be converted to the TC5XX A/D converter input, resulting in an integrator output  $dv/dt$  directly proportional to the magnitude of the applied input voltage. Actual A/D conversion (counting) is initiated at the start of the  $D_{INT}$  phase and terminates when the integrator output crosses 0V. The integrator output is then forced to 0V during the IZ phase and the converter is ready for another cycle. Please see the TC500/TC500A/TC510/TC514 data sheet for a complete description of these phases.

The number of SYSCLK periods (counts) for the AZ and INT phases is determined by the LOAD VALUE. The LOAD VALUE is a single byte that must be loaded into the most significant byte of 16-bit counter on board the TC520A during initialization. The lower byte of this counter is pre-loaded to a value of 0FFH ( $256_{10}$ ) and cannot be changed.

The LOAD VALUE (upper 8 bits of the counter) can be programmed over a range of 0FFH to 00H (corresponding to a range of  $AZ = INT = 256$  counts to 65536 counts). (See Figure 3-2). The LOAD VALUE sets the number of counts for both the AZ and INT phases and directly affects resolution and speed of conversion. The greater the number of counts allowed for AZ and INT, the greater the A/D resolution (but the slower the conversion speed).

The time period required for the  $D_{INT}$  phase is a function of the amount of voltage stored on the integrator during the INT phase and the value of  $V_{REF}$ . The  $D_{INT}$  phase is initiated by the TC520A immediately after the INT phase and terminated when the TC5XX A/D converter changes the state of the CMPTR input of the TC520A, indicating a zero crossing. In general, the maximum number of counts chosen for  $D_{INT}$  is twice that of INT (with  $V_{REF}$  chosen at  $V_{ININ(MAX)}/2$ ). Choosing these values guarantees a full count (maximum resolution) during  $D_{INT}$  when  $V_{IN} = V_{IN(MAX)}$ .

The IZ phase is initiated immediately following the  $D_{INT}$  phase and is maintained until the CMPTR input transitions high. This indicates the integrator is initialized and ready for another conversion cycle. This phase typically takes 2msec.

### 3.3 Serial Port Control Signals

Communication to and from the TC520A is accomplished over a 3 wire serial port. Data is clocked into  $D_{IN}$  on the rising edge of  $D_{CLK}$  and clocked out of  $D_{OUT}$  on the falling edge of  $D_{CLK}$ . READ must be low to read from the serial port and can be taken high at any time, which terminates the read cycle and releases  $D_{OUT}$  to a high impedance state. Conversion data is shifted to the processor from  $D_{OUT}$  in the following order: OVERRANGE (which can also be used as the 17th data bit), POLARITY, conversion data (MSB first).

## 4.0 TYPICAL APPLICATIONS

### 4.1 TC500 Series A/D Converter Component Selection

The TC500/TC500A/TC510/TC514 data sheet details the equations necessary to calculate values for integration resistor ( $R_{INT}$ ) and capacitor ( $C_{INT}$ ), auto zero ( $C_{AZ}$ ) and reference capacitors ( $C_{REF}$ ) and voltage reference ( $V_{REF}$ ). All equations apply when using the TC520A, except Integration time ( $T_{INT}$ ) and Auto zero time ( $T_{AZ}$ ), which are functions of the SYSCLK period (timebase frequency and LOAD VALUE). Microchip offers a ready-to-use TC5XX A/D converter design tool. The TC500 Design Spreadsheet is an Excel-based spreadsheet that calculates values for all components as well as the TC520A LOAD VALUE. It also calculates overall converter performance such as noise rejection, converter speed, etc.

### 4.2 TC520A Initialization

Initialization of the TC520A consists of:

1. Power-On RESET of the TC500/TC520A (forcing the TC520A into an AZ phase).
2. Initializing the TC520A LOAD VALUE.

### 4.3 Power-On RESET

The TC520A powers up with A,B = 00 (IZ Phase), awaiting a high logic state on CMPTR, which must be initiated by forcing the TC520A into the AZ phase. This can be accomplished in one of two ways:

1. External hardware (processor or logic) can momentarily pull LOAD or CE low for a minimum of 100msec ( $T_{AZI}$ ) or;
2. A .01 $\mu$ F RESET capacitor can be connected from CE to  $V_{CC}$  to generate a power-on pulse on CE.

### 4.4 LOAD VALUE Initialization

The LOAD VALUE is the preset value (high byte of the SYSCLK timing counter) which determines the number of counts allocated to the AZ and INT phases of conversion. This value can be calculated using either the TC520A spreadsheet within the TC500 Design Spreadsheet software or can be setup as shown in the following sections.

#### 4.4.1 SELECT $V_{REF}$ , $T_{DEINT}$

Choose the TC5XX A/D converter reference voltage ( $V_{REF}$ ) to be half of the maximum A/D converter input voltage. For example, if  $V_{IN(MAX)} = 2.5V$ , choose  $V_{REF} = 1.25V$ . This forces the maximum de-integration time ( $T_{DEINT}$ ) to be equal to twice the maximum integration time ( $T_{INT}$ ), ensuring a full count (maximum resolution) during DINT.

#### 4.4.2 CALCULATE $T_{INT}$

The TC520A counter length is 16-bits (65536), allowing the full 65536 counts for  $T_{DEINT}$  results in a maximum  $T_{INT} = 65536/2$  or 32768.

#### 4.4.3 SELECT SYSCLK FREQUENCY

SYSCLK frequency directly affects conversion time. The faster the SYSCLK, the faster the conversion time. The upper limit SYSCLK frequency is determined by the worst case delay of the TC500 comparator (which for the TC500 and TC500A is 3.2 $\mu$ sec). While a faster value for SYSCLK can be used, operation is optimized (error minimized) by choosing a SYSCLK period (1/SYSCLK frequency) that is greater than 3.2 $\mu$ sec. Choosing  $T_{SYSCLK} = 4\mu$ sec makes the SYSCLK frequency equal to 250kHz. This makes the external crystal (or frequency source) equal to 1.0MHz, since  $SYSCLK = \text{crystal frequency}/4$ . Calculating integration time (in msec) using  $T_{SYSCLK} = 4\mu$ sec,  $T_{INT} = 4\mu$ sec  $\times$  32768 = 131msec.

#### 4.4.4 CALCULATE LOAD VALUE

Plug the  $T_{INT}$  and  $T_{SYSCLK}$  values into the equation and convert the resulting value to hexadecimal:

#### EQUATION 4-1:

$$\text{LOAD VALUE} = \frac{[(65536 - (T_{INT}/T_{SYSCLK}))]}{256}$$

In this example, LOAD VALUE =  $128_{(10)} = 10H$ . Therefore, a LOAD VALUE of 10H is loaded into the TC520A. If the desired  $T_{INT}$  was 100msec instead of 131msec, the LOAD VALUE would be 9EH, and so on. The TC520A LOAD VALUE must be initialized on power-up, and can be re-initialized as often as desired thereafter. This is accomplished by bringing the LOAD input low while transmitting the appropriate LOAD VALUE to the TC520A as shown in Figure 4-1 and Figure 4-2.

#### 4.4.5 POLLED VS. INTERRUPT OPERATION

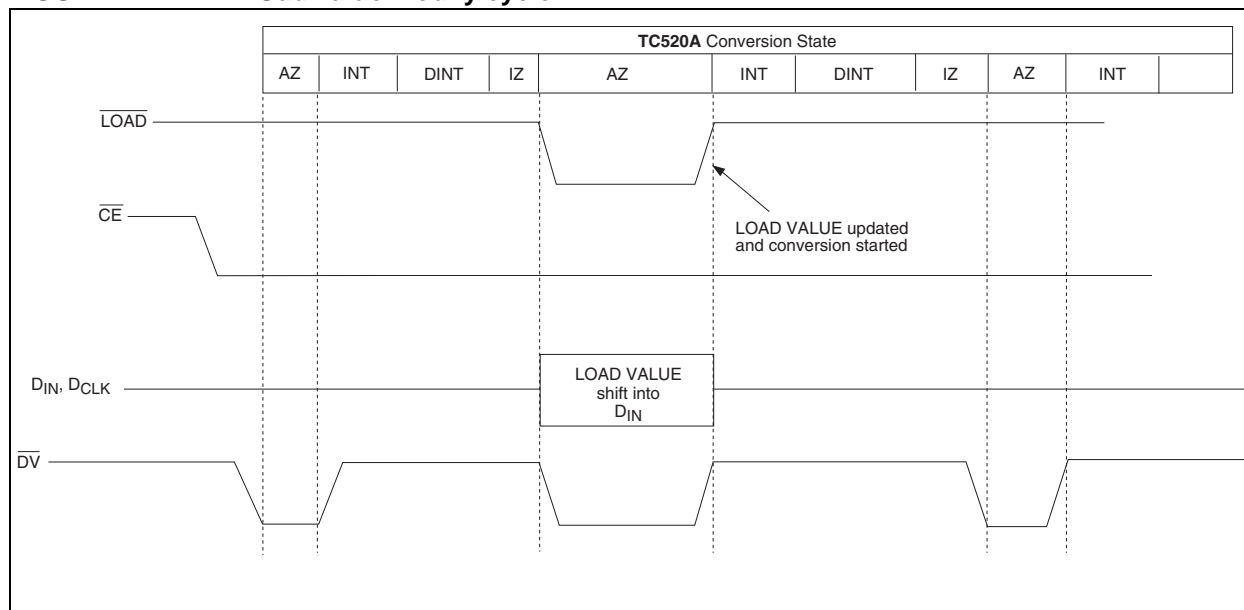

The TC520A can be accessed at any time by the host processor. This makes operation in a polled environment especially easy since the most recently converted data is available to the processor as needed. The TC520A can also be used in an interrupt environment by connecting DV to the IRQ line of the processor. Since AZ is the first phase of a new conversion cycle, the most recently converted data will be available as soon as  $\overline{DV}$  goes low. If so desired, the interrupt service routine can also modify the LOAD VALUE during the  $\overline{DV} = \text{low}$  interval.

# TC520A

**FIGURE 4-1: TC520A initialization & startup conversion timing relationships**

**FIGURE 4-2: Load value modify cycle**

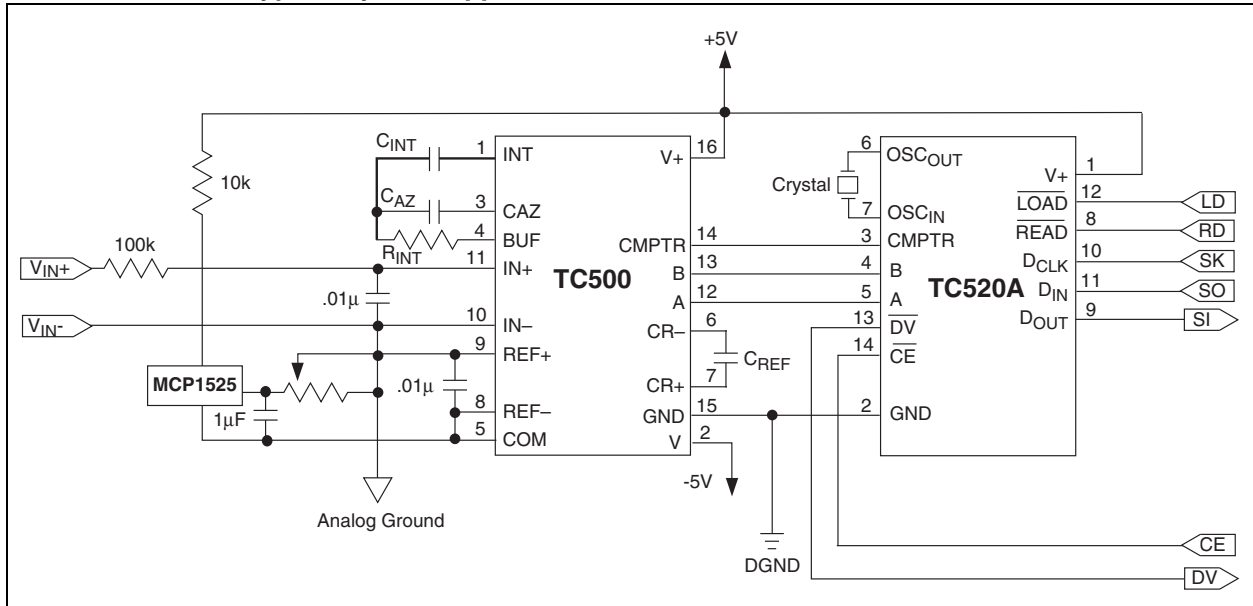

## 4.4.6 OPTO-ISOLATED APPLICATIONS

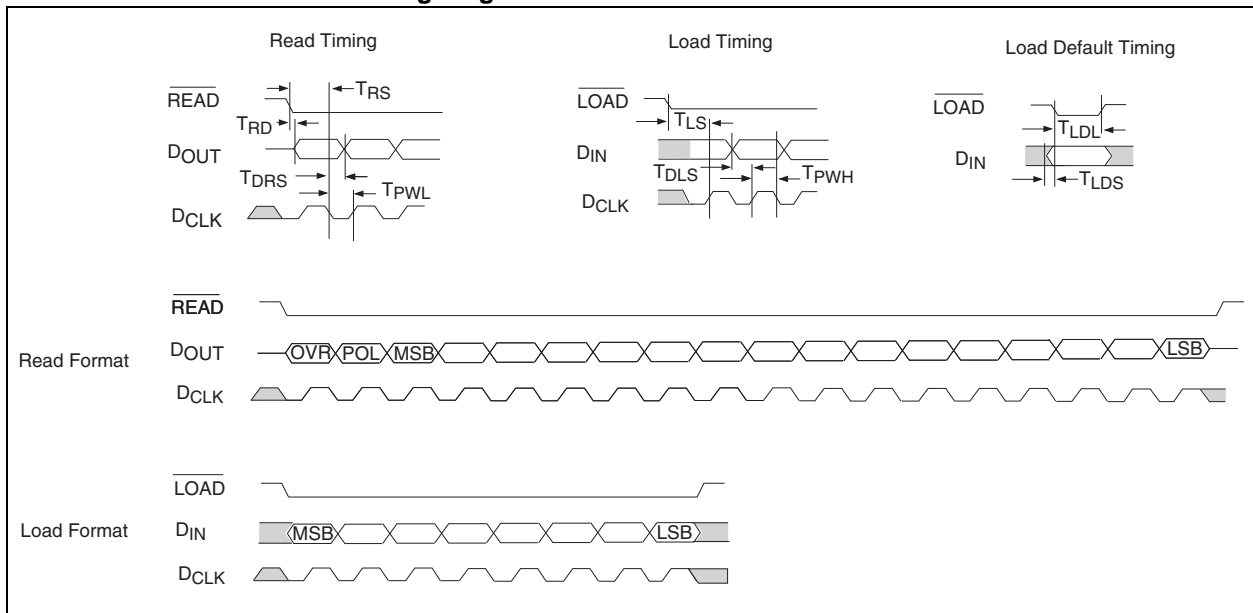

The 3 wire serial port of the TC520A can be opto-isolated for applications requiring isolated data acquisition. The additional control lines ( $\overline{LOAD}$ ,  $\overline{DV}$ ,  $\overline{READ}$ ) are normally not needed in such applications, but can also be brought across the isolation barrier with the addition of a second isolator.

## 6.0 REVISION HISTORY

### Revision C (December 2012)

Added a note to each package outline drawing.

## SALES AND SUPPORT

### **Data Sheets**

Products supported by a preliminary Data Sheet may have an errata sheet describing minor operational differences and recommended workarounds. To determine if an errata sheet exists for a particular device, please contact one of the following:

1. Your local Microchip sales office
2. The Microchip Worldwide Site ([www.microchip.com](http://www.microchip.com))

Please specify which device, revision of silicon and Data Sheet (include Literature #) you are using.

### **New Customer Notification System**

Register on our web site ([www.microchip.com/cn](http://www.microchip.com/cn)) to receive the most current information on our products.

NOTES:

---

**Note the following details of the code protection feature on Microchip devices:**

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.
