### Description

These devices are 16-bit registered transceivers organized as two independent 8-bit bus transceivers designed with three-state D-type flip-flops and control circuitry arranged for multiplexed transmission of data directly from the data bus or from the internal storage registers. Each 8-bit transceiver utilizes the enable control ( $x\bar{OE}$ ) and direction pins ( $xDIR$ ) to control the transceiver functions. The Select ( $xSAB$  and  $xSBA$ ) control pins are used to select either real-time or stored data transfer. The circuitry used for select control will eliminate the typical decoding glitch that occurs in a multiplexer during the transition between real-time and stored data. A low input level selects real-time data and a high selects stored data.

The CD74FCT16646T output buffers are designed with a Power-Off disable allowing "live insertion" of boards when used as backplane drivers.

The CD74FCT162646T has  $\pm 24mA$  balanced output drivers. It is designed with current limiting resistors at its outputs to control the output edge rate resulting in lower ground bounce and undershoot. This eliminates the need for external terminating resistors for most interface applications.

The CD74FCT162H646T has "Bus Hold" which retains the input's last state whenever the input goes to high impedance preventing "floating" inputs and eliminating the need for pull-up/down resistors.

**NOTES:**

1. The data output functions may be enabled or disabled by various signals at the  $x\bar{OE}$  or  $xDIR$  inputs. Data input functions are always enabled, i.e., data at the bus pins will be stored on every low-to-high transition on the clock inputs.

2. Select control = L; clocks can occur simultaneously.

Select control = H: clocks must be staggered in order to load both registers.

H = High Voltage Level

L = Low Voltage Level

X = Don't Care

↑ = LOW-to-HIGH transition
